

After the busbar loses voltage the capacitor

Overview

The operating voltage of the high-voltage capacitor can reflect the voltage status of the busbar system of the substation, and directly affect the life and output function of the capacitor. The active power loss in high-voltage capacitors in operation is mainly composed of two parts: dielectric loss and conductor resistance loss. When the harmonic current in the power grid flows into the capacitor, it will be superimposed on the fundamental wave current of the high-voltage. If the capacitor suddenly loses voltage during operation, it may cause an instantaneous trip on the power supply side of the substation or the disconnection of the main transformer. If, as the temperature rises by 10°C , the capacity of the capacitor decreases twice as fast; if the capacitor is operated under a high electric field and high. The capacitor circuit breaker is mostly a vacuum circuit breaker. When the circuit breaker is closed, the contacts of the circuit breaker may.
