

Charge and plates in a capacitor

Overview

A parallel plate capacitor consists of two plates with a total surface area of 100 cm^2 . What will be the capacitance in pico-Farads, (pF) of the capacitor if the plate separation is 0.2 cm , and the dielectric medium ϵ . Consider the following circuit. Assume that the capacitor is fully discharged and the switch connected to the capacitor has just been moved to position A. The voltage across the $100 \mu\text{F}$. Electrical current can not actually flow through a capacitor as it does a resistor or inductor due to the insulating properties of the dielectric material between the two plates. However. We now know that the ability of a capacitor to store a charge gives it its capacitance value C , which has the unit of the Farad, F. But the farad is an extremely large unit on its own making it. When a capacitor charges up from the power supply connected to it, an electrostatic field is established which stores energy in the capacitor. The amount of energy in Joule.
