

The role of carbon felt in flow batteries

Overview

The graphite composite serves as a robust, conductive backbone that resists the corrosive nature of the electrolyte, while the carbon felt provides a vast, porous network that maximizes the surface area available for electrochemical reactions. However, the electrochemical performance of the original carbon or graphite felt electrodes is not ideal, so it is often. The design parameters of large-scale iron-chromium redox flow batteries (ICRFB) encompass a wide range of internal and external operational conditions, including electrodes, membranes, flow rate, and temperature, among others. Among these factors, the intrinsic structures of graphite felt (GF) and. Surface modification of carbon felt with high conductivity, thermal stability, and specific surface area of carbon nanotubes can effectively improve the overall conductivity, thermal stability, and specific surface area of carbon felt, while improving its hydrophilicity and surface resistance. In this study, the chemical mechanisms for carbon electrode degradation are investigated and distinct differences in the degradation.
